AI in Human Resources & Talent Management

Problem Statement:

A large Indian IT company wants to reduce employee turnover, improve hiring quality, and enhance employee engagement. Create an AI strategy for unbiased recruitment, attrition prediction, and personalized employee development.

Example: Infosys (India), Accenture (Global), Naukri.com (India)

Subject: Introduction to AI

Submitted to: Mr. Chintan Patel

Enrollment no: 20261038

Executive Summary:

A large Indian IT company that depends on people with the right skills struggles to hire at scale and retain experienced employees. Recruitment teams can get thousands of applications for a single job opening, and employees can become disengaged when workloads are high or career development seems slow. This report sets out an AI strategy with three linked aims – fairer recruitment, early support for those employees who may leave, and learning tailored to each person's skillset and career interests.

The proposed method includes AI-enhanced candidate matching, a closely monitored attrition risk model, and a customized learning and internal mobility system. Infosys is a good example of how artificial intelligence can be used to improve learning and employee experience. Accenture is a global reference for skills-based workforce transformation and learning. And AI REX from Naukri.com is a good example of how agentic AI can help recruiters source and screen candidates more efficiently. These are examples to use as benchmarks, not to say that the company being proposed should copy every feature.

The conclusion is that we have to hold people accountable for decisions. AI can help organize information and recognize patterns but should not be used to reject candidates, penalize employees or make promotion decisions on its own, it's not just how much is automated, but the quality of hires, fairness, trust in employees, internal mobility and retention.

1. Problem Context and Objectives:

The problem statement identifies three HR outcomes: reduce employee turnover, improve hiring quality, and increase engagement. These results affect each other, Poor hiring matches can lead to early resignations, limited development can drive skilled employees to look elsewhere, and rushed recruitment can increase the likelihood of inconsistent decisions.

The trial report highlights high-volume recruitment, possible disadvantages for Tier-2 and Tier-3 college applicants, and language barriers in screening. These are useful risks to test in an Indian IT setting, but figures in the trial report should not be treated as verified industry-wide statistics unless the original study can be checked. The strategy below therefore uses the report's themes while proposing that the company establish its own base-line before claiming measurable improvement.

What this report aims to do

- Suggest a fair way to use AI during recruitment.
- Explain how AI could help HR notice possible employee turnover earlier.
- Recommend a learning system that considers each employee's skills and interests.
- Identify risks and suggest practical checks before the company expands the system.

2. How AI can support HR

I would use three main AI ideas for this problem. The first is Natural Language Processing (NLP), which helps a computer work with written or spoken language. In recruitment, it can

help read resumes and compare them with job requirements. The second is machine learning, which can learn patterns from past data and estimate possible outcomes. It could be used to study patterns linked with employee resignations. The third is a recommendation system, which can suggest learning courses, mentors or internal job openings based on an employee's skills.

Generative AI can also be useful. For example, an employee could ask a chatbot to explain a company policy or help them understand a technical concept. However, the answer should be checked against approved company information, especially when the question concerns salary, leave or other important HR policies. (See Appendix-A)

2.1 Important point: a prediction is not a fact

An AI system works with the data it has been given. If the data is incomplete or biased, its output can also be wrong. A high attrition score does not prove that an employee is planning to resign. It only means that some information resembles patterns found in earlier cases. In the same way, a low resume score does not automatically mean that a candidate is unsuitable.

Because of this, I recommend a human-in-the-loop approach. AI can help organize information and point out possible patterns, but people should check the results before making decisions that affect someone's job of career.

3. Pillar One: Fair Recruitment and Better Hiring Quality

3.1 Suggested recruitment process:

The company should begin by making the job requirements clear. The hiring manager and recruiter should decide which skills are essential and which can be learned after joining. AI can help prepare a job description, but the final criteria should be approved by the people responsible for the role.

• Step 1 – Resume reading: NLP can identify a candidate's skills, projects, qualifications and experience from different resume formats.

• Step 2 – Skills matching: the system compares the information with the approved job criteria. It should not give extra marks just because a candidate studied at a famous college.

• Step 3 – Structured questions: candidates applying for the same role should receive the same main questions and be assessed using the same scoring guide.

• Step 4 – Human review: recruiters review the shortlisted profiles and check whether the AI has missed a suitable candidate.

• Step 5 – Review the results: HR checks whether some groups of candidates are being rejected more often and investigates the reasons.

3.2 What Naukri.com can teach us

Naukri.com's AI REX is presented as an AI-based talent-sourcing platform that helps with tasks such as defining requirements, finding candidates and supporting recruiter workflows. (See Appendix B). This is relevant because recruiters often spend a lot of time searching for

profiles and following up with candidates. Automating some of these repetitive tasks could give recruiters more time to speak with suitable applicants.

However, faster screening does not automatically mean fair screening. If a system is trained on previous hiring decisions, it may learn the same preferences that existed in the old process. For example, it may favor applicants from colleges that the company hired from most often. To reduce this risk, the company should focus on skills, use a clear scoring guide and check the system regularly.

3.3 How I would measure success

- How long it takes to shortlist and fill a vacancy.
- Whether new employees meet the role's requirements after joining.
- Candidate feedback and the number of candidates who stop midway through the process.
- Whether the selection process creates unexplained differences between candidate groups.

I would first test the process on a small number of job roles. The company should compare the AI-supported process with its existing process before using it for all vacancies. The aim should be to find suitable candidates more consistently, not simply to reject applications faster.

4. Pillar Two: Predicting Attrition and Supporting Employees

Employee turnover can create extra recruitment costs and can also affect project delivery because experienced employees take their knowledge with them. Most companies learn the full reason for leaving during an exit interview, which happens after the decision has already been made. AI may help HR notice warning signs earlier, giving the company a chance to improve the employee's experience.

4.1 What information could be used?

The company could study appropriate work-related information, such as time in the current role, workload trends, project allocation, promotion history, internal job applications and voluntary engagement survey responses. It should avoid collecting private information that is not needed for this purpose.

A machine-learning model could use part records to estimate which patterns are associated with voluntary resignation. Before using it, the company should test whether it works on a later period of data, not only on the data used to train it. HR should also check whether it is reliable for different job roles and teams.

4.2 What should happen when risk is high?

In my proposed system, a high-risk result would lead to supportive conversation, not a warning or punishment. A manager could ask whether the employee has too much work, needs a new challenge, wants to learn another skill or is facing a problem with their current project. The next step should depend on what the employee says, rather than on the AI score alone. (See, Appendix C)

4.3 Risks and Safeguards

A prediction can be wrong. If managers treat a risk score as a label, employees may lose trust in the company. Therefore, I would not allow attrition scores to be used for termination, negative performance reviews, bonus decisions or denying promotion. Access should be restricted to authorized HR staff, and employees should be informed about the purpose of the system.

The company should measure voluntary attrition before and after the pilot, but it should not promise a specific reduction before collecting its own results. Pay changes, project conditions and the job market can also affect turnover, so the company must consider these factors when judging whether the AI strategy helped.

5. Pillar Three: Personalized Development and Engagement

In IT, skills can become outdated as tools and client requirements change. If employees do not know what to learn next or cannot find opportunities to use new skills, they may feel stuck. A personalized development system could help employees understand their skill gaps and find learning that is relevant to their goals.

5.1 How it could work

- Build a skills profile using information such as completed training, certifications, project experience and employee-confirmed skills.
- Ask employees about their interests and the type of role they would like to work towards.
- Recommend a small number of relevant courses, practice tasks or mentors instead of giving everyone the same training list.
- Suggest internal roles or projects where the employee could use their existing skills and develop new ones.
- Review the plan with the employee and manager and update it as the employee's goals change.

5.2 Lessons from Infosys and Accenture

Infosys is a useful example because of its LEX learning platform is associated with employee learning and personalized development. Its employee experience work also shows how digital tools can make everyday HR services easier to access. (See Appendix B). For the proposed company, the lesson is to connect learning with an employee's current skills and future work, rather than treating training as a one-time activity.

Accenture's Learn Vantage work focuses on learning and building skills for a changing business and technology needs (See Appendix B). I take this as a reminder that reskilling needs support from the company, not only effort from individual employees. Employees need time to

learn, managers need to encourage them, and the organization needs projects where those new skills can be used.

5.3 How to know if development is working

- Employees complete relevant training and can show how they used it in their work.
- Employees gain access to suitable internal projects or job opportunities.
- Employees report that the recommendations are useful and relevant to their goals.
- HR monitors whether engagement and retention improve over time.

Course completion alone is not enough. The company should also ask whether employees found the training useful and whether they had a chance to apply what they learned. In my view, a learning platform is more valuable when it helps employees move forward in careers.

6. Implementation and Responsible AI

I would not recommend launching all three systems across the whole company at once. A small pilot would make it easier to find data problems, collect employee feedback and fix issues before expanding. The company should involve HR, IT, legal and business managers from the beginning (Appendix D).

6.1 Privacy and fairness:

Candidate and employee information should be used only for a clear purpose, kept secure and accessed only by people who need it. The company should provide clear information about how AI is used and give people a way to ask questions or request a human review. Its legal team should check the requirements that apply under India's Digital Personal Data Protection Act, 2023, and the rules in force when the system is introduced. (See Appendix A).

The company should also test the system for bias before launch and at regular intervals. A quarterly review could look at rejection patterns, model accuracy, employee feedback and any privacy incidents. If the company cannot explain why the system produced an important recommendation, it should not rely on that recommendation for a high-impact decision.

6.2 Measures to track

The company should record the current position before the pilot starts. Targets should be set after the baseline is understood. This is more reliable than copying a percentage from another company, because the size of the workforce, job types and working conditions may be different (See Appendix E).

7. Conclusion and My Recommendations

After considering the three parts of the problem, I believe AI can be useful in HR if the company uses it carefully. In recruitment, it can reduce repetitive work and help recruiters focus on skills, but people must check the results for unfair patterns. In attrition management, it can help HR notice possible problems earlier, but it should lead to a conversation and support rather

than punishment. In employee development, it can suggest learning and internal roles that match an employee's interests and the company's needs.

The three examples support different parts of this strategy. Naukri.com is relevant to sourcing and recruitment workflows, Infosys provides an example of digital employee services and learning, and Accenture highlights the importance of building skills continuously. I would use these examples as starting points, then test the proposed approach with the company's own employees and data.

My five recommendations:

- Start with a small pilot and measure the current situation before setting targets.
- Assess candidates against clear job-related skills and keep final hiring decisions with recruiters.
- Use attrition predictions only to offer support and never as a reason to penalize an employee.
- Personalise training around employees' goals and provide real opportunities to use new skills.
- Have HR, IT and legal teams review privacy, fairness and performance regularly.

The most important point is that AI should support people, not replace the responsibility of managers and HR teams. A successful strategy should make hiring fairer, help employees feel supported and give them a clearer chance to grow within the organization.

Appendices:

Appendix A: How AI can help HR

HR need	AI method	What a person still needs to do
Recruitment	NLP to read resumes and match skills with job requirements	Recruiter checks the evidence and conducts interviews
Attrition	Machine learning to identify patterns linked with resignations	Manager talks to the employee and understands the reason
Development	Recommendation system for courses, mentors and internal roles	Employee and manager agree on a realistic development plan
Responsible use	Reports, access controls and bias checks	HR, IT and legal teams review how the system is used

Appendix B: Company Benchmark Summary

This table summaries the examples referred to in the report. The company examples are used as benchmarks, the recommendations are my proposed approach for the case company.

Company	What the report uses as an example	How the case company could apply the lesson
Infosys (India)	LEX learning and digital employee experience tools.	Connect employee skills, learning suggestions and HR services is an accessible system.

Accenture (Global)	Learn Vantage and its focus on workforce learning.	Make reskilling continuous and connect training with changing technology needs.
Naukri.com (India)	AI REX for AI-supported sourcing and recruiter workflows.	Reduce repetitive sourcing tasks while keeping recruiter review and fairness checks.

Appendix C:

Possible issue noticed	Supportive action HR or manager could consider
Workload has remained high	Review deadlines, workload and project staffing
Employee has been in the same role for a long time	Discuss a new project, role rotation or promotion criteria
Skills do not match future project needs	Offer relevant training, mentoring or certification support
Employee reports low engagement	Have a confidential conversation and agree on follow-up actions

Appendix D: Implementation and Responsible AI

Time Period	Suggested Work	Check before moving ahead
Months 1-3	Review data quality, decide responsibilities, set baseline measures and privacy rules.	The purpose, data access and review process are documented.
Months 4-6	Test AI-supported recruitment for a small group of roles.	Recruiters review results and check hiring quality and fairness.
Months 7-9	Pilot attrition support and personalized learning in selected teams.	Employees understand the purpose and risk scores are not used to punish people.
Months 10-12	Review results, correct problems and expand only if the pilot is useful.	HR, IT and legal approve the next stage after checking the evidence.

Appendix E: Measures to track

Area	Measures to review
Recruitment	Time to fill, quality of hire, candidate feedback and selection patterns
Retention	Voluntary attrition, retention after support and internal mobility
Development	Skill improvement, usefulness of training and use of new skills at work
Responsible AI	Human reviews completed, bias checks, complaints and data incidents

Appendix F: Proposed HR AI Process

Process	AI Support	Human Check	Expected Benefit
Recruitment	Parse resumes and match job-related skills	Recruiter reviews evidence, scores and exceptions	More consistent screening and less manual sorting
Attrition	Identify work-related patterns linked with voluntary exits	HR/manager checks context and offers support	Earlier conversations and more targeted retention actions
Development	Suggest courses, mentors and internal opportunities	Employee and manager agree on the plan	Learning that is more relevant to career goals
Governance	Create logs and reports for system monitoring	HR, IT and legal review results and incidents	Better accountability, privacy and fairness
